

A FREE GUIDE

How I Build Websites Without Writing Code

A Free Resource from The Lazy Creator Co.

THE LAZY CREATOR CO.

Welcome

Hi, I'm Michael — the person behind The Lazy Creator Co. Everything you're looking at right now, this site included, was built this way: no code editor, no local dev environment, just me directing AI tools from my phone and verifying every change before it goes live. This guide is the actual workflow, not a sales pitch for a course that doesn't exist yet.

If you want a site built this same way instead of building it yourself, that's real freelance work I take on — see the [Websites & Freelance](#) page for details.

SECTION 1

The Stack I Actually Use

I don't have a dev environment. No local server, no IDE plugins, none of it. The whole thing runs on three pieces: a GitHub repo for the code, Netlify for hosting and forms, and an AI tool I direct to actually write and edit the code. That's the entire stack.

Netlify's free tier hosts the site, handles the SSL certificate, and runs the contact forms without a backend. GitHub stores every version so nothing is ever truly lost — if a change breaks something, I can always see exactly what changed and undo it.

Key Takeaway

You don't need a laptop full of developer tools to ship a real, production website. You need a place to store the code, a place to host it, and something that can actually write it.

SECTION 2

How a Page Actually Gets Built

Every change follows the same loop. I describe exactly what needs to happen — not the code, just the outcome. The AI makes the change. Then I verify it actually worked before it goes anywhere near the live site — a screenshot, a rendered preview, a functional test, whatever proves the change did what it was supposed to do.

Only after it's verified does it get committed and pushed. This loop is the entire job: describe, build, verify, ship. Skip the verify step and you're just hoping it works, which is how sites quietly break in ways nobody notices for weeks.

Key Takeaway

Verification isn't optional overhead — it's the step that lets you move fast without breaking things. Never ship a change you haven't actually seen work.

SECTION 3

Three Mistakes I'd Avoid Starting Out

Building features before you need them. It's tempting to add a members area, a blog, a search bar — before a single real visitor has shown up. Build the page that gets someone to take one action. Add the rest when you actually need it.

Ignoring mobile until the end. Most of your traffic will be on a phone. If you only check desktop while building, you'll find out the hard way that your nav is broken on the device most people are actually using.

Not verifying before you push. The fastest way to lose trust in your own site is to ship something broken and find out from a visitor instead of catching it yourself first.

SECTION 4

What This Actually Costs

The honest answer: very little, at small scale. Netlify's free tier covers hosting, forms, and SSL for a site like this one. GitHub is free for a solo project. The only real recurring cost is whatever AI tool you're using to direct the actual building — and that's a fraction of what a single freelance developer invoice would run.

This isn't about avoiding developers forever. It's about not needing one to get a real site live, tested, and taking real visitors today.

Want One Built For You

This guide is the process. If you'd rather have it done than do it yourself, The Lazy Creator Co. takes on freelance website builds using exactly this workflow — fast, verified, and live.
